1 Topological Spaces

Definition 1.1. A **topology** on a set X is a collection \mathcal{T} of subsets of X such that:

- $\emptyset, X \in \mathcal{T}$.
- The union of (possibly uncountably many) sets in \mathcal{T} is in \mathcal{T} .
- The intersection of finitely many sets in \mathcal{T} is in \mathcal{T} .

A set X for which a topology has been specified is called a **topological space**. Elements of \mathcal{T} are called **open sets** of X . The complements of open sets of X are called **closed sets** of X . Sets that are both open and closed in X are called **clopen** in X . For any $x \in X$, a **neighborhood** of x is an open set of X containing x .

Example 1.1.

1. The **discrete topology** on X is $\mathcal{P}(X)$, i.e. all subsets of X are open in X .
2. The **indiscrete (or trivial) topology** on X is $\{\emptyset, X\}$.
3. The **finite complement topology** on X is $\{\emptyset\} \cup \{A \subseteq X : X \setminus A \text{ is finite}\}$. The **countable complement topology** on X is $\{\emptyset\} \cup \{A \subseteq X : X \setminus A \text{ is countable}\}$.

Exercise. Show that the above are valid topologies.

Definition 1.2. Suppose \mathcal{T} and \mathcal{T}' are topologies on X .

- We say \mathcal{T} is **finer** than \mathcal{T}' if $\mathcal{T} \supseteq \mathcal{T}'$. (Draw a diagram to visualize)
- We say \mathcal{T} is **coarser** than \mathcal{T}' if $\mathcal{T} \subseteq \mathcal{T}'$.
- We say \mathcal{T} and \mathcal{T}' are **incomparable** if neither $\mathcal{T} \supseteq \mathcal{T}'$ nor $\mathcal{T} \subseteq \mathcal{T}'$.

Definition 1.3. A (topological) **basis** on X is a collection \mathcal{B} of subsets of X where

- $\bigcup_{B \in \mathcal{B}} B = X$. (\mathcal{B} **covers** X , i.e. every $x \in X$ belongs to some $B \in \mathcal{B}$)
- Any x in two basis elements B_1, B_2 belongs to some basis element $B_3 \subseteq B_1 \cap B_2$.

The **topology generated by** \mathcal{B} consists of all possible *unions* of elements in \mathcal{B} .

Theorem 1.1. The topology \mathcal{T} generated by a basis \mathcal{B} is in fact a topology on X .

Proof. Firstly, $\emptyset \in \mathcal{T}$ since it is the empty union. Also, $X \in \mathcal{T}$ because \mathcal{B} covers X . We then verify the union and intersection properties:

- Given any $\{U_\alpha\}_\alpha \subseteq \mathcal{T}$, each U_α is a union of elements in \mathcal{B} , so $\bigcup_\alpha U_\alpha$ is also a union of elements in \mathcal{B} , and hence is in \mathcal{T} .
- Given any $U_1, U_2 \in \mathcal{T}$, we show that $U_1 \cap U_2 \in \mathcal{T}$: Let $x \in U_1 \cap U_2$, then x belongs to some basis element $B_1 \subseteq U_1$ and some basis element $B_2 \subseteq U_2$. Hence x belongs to some basis element $B(x) \subseteq B_1 \cap B_2 \subseteq U_1 \cap U_2$. Now, $U_1 \cap U_2 = \bigcup_{x \in U_1 \cap U_2} B(x)$ and thus $U_1 \cap U_2 \in \mathcal{T}$. The general finite intersection case follows from induction. ■

Corollary 1.1. Suppose we have a topology with some basis \mathcal{B} . Given any open set U and an element $x \in U$, there exists some basis element $B \in \mathcal{B}$ such that $x \in B \subseteq U$.

We can often reduce a problem about open sets to one about just the basis elements:

Theorem 1.2. Let \mathcal{T} and \mathcal{T}' be topologies on X with bases \mathcal{B} and \mathcal{B}' respectively. Then \mathcal{T}' is finer than \mathcal{T} if and only if for every possible $x \in B \in \mathcal{B}$ there exists $B' \in \mathcal{B}'$ such that $x \in B' \subseteq B$. (We can always get a smaller one in \mathcal{B}')

Definition 1.4.

- The **standard topology** on \mathbb{R} is the topology generated by the collection of open intervals $(a, b) = \{x : a < x < b\}$. This is the default topology we assume.
- The **lower-limit topology** on \mathbb{R} is the topology generated by the collection of half-open intervals $[a, b) = \{x : a \leq x < b\}$. We write $\mathbb{R} = \mathbb{R}_\ell$ in this case.
- The **K-topology** on \mathbb{R} is the topology generated by all open intervals (a, b) and sets of the form $(a, b) \setminus \{1/n : n \in \mathbb{N}^*\}$. We write $\mathbb{R} = \mathbb{R}_K$ in this case.

By Theorem 1.2, we can show that \mathbb{R}_ℓ and \mathbb{R}_K are strictly finer than \mathbb{R} , but are incomparable.

Generalizing from Definition 1.3, we can generate a topology from any collection of subsets that covers X (i.e. without necessarily having the second condition).

Definition 1.5. Let \mathcal{S} be a collection of subsets of X that covers X . The **topology generated by \mathcal{S}** is the collection of all possible unions of all possible *finite intersections* of elements in \mathcal{S} . We say that \mathcal{S} is a **subbasis** of this topology.

2 Order, Product, and Subspace Topology

Definition 2.1. Let X have a simple order relation $<$. The *intervals* of X are:

$$\begin{aligned} (a, b) &= \{x \in X : a < x < b\} & [a, b) &= \{x \in X : a \leq x < b\} \\ (a, b] &= \{x \in X : a < x \leq b\} & [a, b] &= \{x \in X : a \leq x \leq b\} \end{aligned}$$

and the *rays* of X are:

$$\begin{aligned} (a, +\infty) &= \{x \in X : x > a\} & (-\infty, a) &= \{x \in X : x < a\} \\ [a, +\infty) &= \{x \in X : x \geq a\} & (-\infty, a] &= \{x \in X : x \leq a\} \end{aligned}$$

The *order topology* on an ordered set X is the topology generated by the basis consisting of open intervals (a, b) and open rays $(a, +\infty), (-\infty, a)$.

Example 2.1.

1. The order topology on \mathbb{R} is the standard topology.
2. The order topology on \mathbb{Z} is the discrete topology.
3. The order topology on $\{1, 2\} \times \mathbb{N}^*$ is *not* the discrete topology. Which one-point set is not open?

Definition 2.2. Let $X = \prod_{\alpha \in J} X_\alpha$ be a cartesian product of sets $\{X_\alpha\}_{\alpha \in J}$. The *projection* of X onto index β is the function $\pi_\beta((x_\alpha)_{\alpha \in J}) = x_\beta$.

Definition 2.3. Let X, Y be topological spaces. The *box/product topology* on $X \times Y$ is generated by the basis $\{U \times V : U, V \text{ are open in } X, Y \text{ respectively}\}$

This definition can generalize to finite cartesian products. However, for infinite cartesian products, there is a distinction between box and product topologies:

Definition 2.4. Let $\{X_\alpha\}_{\alpha \in J}$ be a collection of topological spaces.

- The *box topology* on $\prod_{\alpha \in J} X_\alpha$ is the topology generated by the basis $\{\prod_{\alpha \in J} U_\alpha : U_\alpha \text{ is open in } X_\alpha \text{ for all } \alpha\}$.
- The *product topology* on $\prod_{\alpha \in J} X_\alpha$ is the topology generated by the basis $\{\prod_{\alpha \in J} U_\alpha : U_\alpha \text{ is open in } X_\alpha \text{ for all } \alpha, \text{ but only finitely many } \alpha \text{ satisfy } U_\alpha \neq X_\alpha\}$.

For reasons to be seen, the product topology is the most preferred one.

Theorem 2.1. $\bigcup_{\beta \in J} \{\pi_{\beta}^{-1}(U_{\beta}) \mid U_{\beta} \text{ open in } X_{\beta}\}$ is a subbasis for the product topology.

Definition 2.5. Let Y be a subset of a topological space X . The **subspace topology** on Y (with respect to X) consists of sets of the form $Y \cap U$ where U is open in X , i.e.

$$V \text{ open in } Y \Leftrightarrow V = Y \cap U \text{ where } U \text{ open in } X$$

Example 2.2. $[0, 1]^2$ as a subspace of the dictionary ordered \mathbb{R}^2 and as its own dictionary order topology are different! The set $\{0.5\} \times (0.5, 1]$ is open in the former topology but not in the latter. The latter topology is called the **ordered square** I_o^2 .

3 Limit Points

Definition 3.1. Let A be a subset of a topological space X .

- The **interior** of A , denoted $\text{Int}(A)$ or $\overset{\circ}{A}$, is the largest open set contained in A .
- The **closure** of A , denoted \overline{A} , is the smallest closed set that contains A .

Definition 3.2. Let A be a subset of a topological space X . We say that $x \in X$ is a **limit point** of A if every neighborhood of x intersects $A \setminus \{x\}$.

Theorem 3.1. $\overline{A} = A \cup \{\text{limit points of } A\}$.

Proof.

- (\subseteq) We prove that if $a \in \overline{A} \setminus A$, then a is a limit point of A . Let U be any neighborhood of a . If $U \cap A = \emptyset$, then $X \setminus U$ is a closed set containing A , so $\overline{A} \cap (X \setminus U)$ is a smaller (no a) closed set than \overline{A} containing A , a contradiction. Hence $U \cap A \neq \emptyset$.
- (\supseteq) Since $A \subseteq \overline{A}$, it suffices to show that all limit points of A are in \overline{A} . Let a be a limit point of A . If $a \notin \overline{A}$, then a lies in the open set $X \setminus \overline{A}$ and hence has a neighborhood $U \subseteq X \setminus \overline{A}$. This means $U \cap \overline{A} = \emptyset \Rightarrow U \cap A = \emptyset$, contradiction. ■

Corollary 3.1. A set is closed if and only if it contains all its limit points.

Definition 3.3. A space X is **Hausdorff** if for each pair of distinct points $x_1, x_2 \in X$, there exist neighborhoods U_1, U_2 respectively that are disjoint.

Theorem 3.2.

- Every neighborhood of a limit point of a subset A of a Hausdorff space intersects A at *infinitely many* points.
- A sequence of points in a Hausdorff space converges to at most one point of X .

4 Continuous Functions

Definition 4.1. Let X, Y be topological spaces. A function $f : X \rightarrow Y$ is

- **continuous at $x \in X$** if $f^{-1}(V)$ is open in X for all neighborhoods V of $f(x)$.
- **continuous** if $f^{-1}(V)$ is open in X for all V open in Y .
- a **homeomorphism** if f is bijective, and f and f^{-1} are continuous.

Theorem 4.1.

- In both box/product topologies, if all X_α are Hausdorff, $\prod_{\alpha \in J} X_\alpha$ is Hausdorff.
- In both box/product topologies, $\prod_{\alpha \in J} \overline{A_\alpha} = \overline{\prod_{\alpha \in J} A_\alpha}$.
- In just the product topology, $f = (f_\alpha)_{\alpha \in J} : A \rightarrow \prod_{\alpha \in J} X_\alpha$ is continuous if and only if each f_α is continuous.

5 Metric Topology

Definition 5.1. A **metric** on X is a function $d : X^2 \rightarrow \mathbb{R}$ such that

- $d(x, y) \geq 0$ for all $x, y \in X$ and equality holds if and only if $x = y$.
- $d(x, y) = d(y, x)$ for all $x, y \in X$.
- $d(x, y) + d(y, z) \geq d(x, z)$ for all $x, y, z \in X$.

$d(x, y)$ is called the **distance** between x and y . The set $B_d(x, \varepsilon) = \{y : d(x, y) < \varepsilon\}$ is called the (open) **ε -ball centered at x** .

Definition 5.2. The *metric topology* induced by a metric d on X is the topology generated by the collection of all open balls. A topological space X is said to be *metrizable* if there exists some metric that induces the topology of X .

Theorem 5.1. Given a metric d on X , the metric $\bar{d}(x, y) = \min \{d(x, y), 1\}$ induces the same topology as d does.

Example 5.1.

1. The *euclidean metric* d on \mathbb{R}^n is $d(\mathbf{x}, \mathbf{y}) = \sqrt{(x_1 - y_1)^2 + \cdots + (x_n - y_n)^2}$.
2. The *standard uniform metric* \bar{d} on \mathbb{R} is $\bar{d}(x, y) = \min \{|x - y|, 1\}$.
3. The *uniform metric* $\bar{\rho}$ on \mathbb{R}^J (for any index set J) is $\bar{\rho}(\mathbf{x}, \mathbf{y}) = \sup_{\alpha \in J} \bar{d}(x_\alpha, y_\alpha)$.
4. The metric $D(\mathbf{x}, \mathbf{y}) = \sup_i \left\{ \frac{\bar{d}(x_i, y_i)}{i} \right\}$ induces the product topology on \mathbb{R}^ω .

6 Quotient Topology

Definition 6.1.

- Let X, Y be topological spaces. A surjective map $p : X \rightarrow Y$ is a *quotient map* if ‘ U is open in Y if and only if $p^{-1}(U)$ is open in X ’. In other words, p is a quotient map if and only if p is continuous and maps *saturated* (some union of $p^{-1}(\{y\})$) open sets of X to open sets of Y .
- Let X be a space, A be a set, and $p : X \rightarrow A$ be surjective. The *quotient topology* induced by p is the unique topology on A where p is a quotient map.
- Let X be a space and X^* be a partition of X . X^* is a *quotient space* of X , under the quotient topology induced by the natural mapping $p : X \rightarrow X^*$.

Example 6.1. Consider the unit 2-disk $X = D_2 = \{x \times y : x^2 + y^2 \leq 1\}$. We let X^* be the partition of X consisting (i) the boundary $S^1 = \{x \times y : x^2 + y^2 = 1\}$, and (ii) the singleton sets $\{x \times y\}$ for all interior points $x^2 + y^2 < 1$. Then we can show that the quotient space X^* is homeomorphic with the subspace of \mathbb{R}^3 called the unit 2-sphere $S^2 = \{x \times y \times z : x^2 + y^2 + z^2 = 1\}$. (See diagram below)

Using similar ideas, we can construct a *torus* from the rectangle $[0, 1] \times [0, 1]$.

Theorem 6.1. Let $p : X \rightarrow Y$ be a quotient map. Let Z be a space and let $g : X \rightarrow Z$ be a map that is constant on each one-point preimage $p^{-1}(\{y\})$. Therefore g induces a map $f : Y \rightarrow Z$ where $f \circ p = g$. Then

- f is continuous if and only if g is continuous.
- f is a quotient map if and only if g is a quotient map.

$$\begin{array}{ccc}
 X & & \\
 p \downarrow & \searrow g & \\
 Y & \xrightarrow{f} & Z
 \end{array}$$

7 Connectedness

Definition 7.1. A topological space X is said to be **connected** if there is no nontrivial clopen set A . (Equivalently, there is no $A \notin \{\emptyset, X\}$ where A and $X \setminus A$ are both open.)

Example 7.1. The subspace $(0, 1) \cup (2, 3)$ of \mathbb{R} is not connected.

Theorem 7.1.

- Let C be clopen in X . Any connected subspace of X lies within either C or $X \setminus C$.
- The union of connected subspaces that have a common point is connected.
- If A is a connected subspace of X and $A \subseteq B \subseteq \overline{A}$ then B is connected.

- A continuous function maps a connected space to a connected image.
- A cartesian product of connected spaces (in the product topology) is connected.

Definition 7.2. A simply ordered set L with more than one element is a **linear continuum** if (i) L has the least upper bound property, and (ii) for any $x < y$ there exists $x < z < y$.

Theorem 7.2. In an order topology, linear continuums, and intervals and rays in a linear continuum are connected. (Hence intervals in \mathbb{R} are connected.)

Theorem 7.3. (Intermediate Value Theorem)

Let $f : X \rightarrow Y$ be continuous, X is connected, and Y is ordered. If $a, b \in X$ and r is a point lying between $f(a), f(b)$, then there exists $c \in X$ such that $f(c) = r$.

Path-Connectedness

Definition 7.3. A space is **path-connected** if every pair $x, y \in X$ can be joined by a *path* in X : a continuous map $f : [0, 1] \rightarrow X$ such that $f(0) = x$ and $f(1) = y$.

Example 7.2. All path-connected spaces are connected. The converse is not true, e.g. the ordered square and the topologist's sine curve

Components and Path Components

Definition 7.4. The equivalence relation $x \sim y$ where there is a (path-)connected subspace containing both x, y partitions the space into (path-)connected **components**.

Local Connectedness

Definition 7.5. A space is *locally (path-)connected at x* if for every neighborhood U of x , there is a (path-)connected neighborhood V of x contained in U .

8 Compactness

Definition 8.1. An *open covering* of X is a collection of open sets that cover X . A space X is *compact* if every open covering of X admits a finite subcovering.

Theorem 8.1.

- Every closed subspace of a compact space is compact.
- If Y is a compact subspace of a Hausdorff space and $x_0 \notin Y$, there exists disjoint open sets U, V containing $\{x_0\}$ and Y respectively.
- Every compact subspace of a Hausdorff space is closed.
- A continuous function maps compact spaces to a compact image.

Theorem 8.2. (Tychonoff Theorem)

A cartesian product of compact spaces is compact.

Compactness via Closed Sets

Definition 8.2. A collection \mathcal{C} of subsets of X has the *finite intersection property* if every finite subcollection has nonempty intersection.

Theorem 8.3. X is compact if and only if for every collection \mathcal{C} of closed sets having the finite intersection property, the intersection $\bigcap_{C \in \mathcal{C}} C$ is nonempty.

Compactness on \mathbb{R}^n

Theorem 8.4. Let X be a simply ordered set having the least upper bound property. Every closed interval in X is compact.

Theorem 8.5. (Heine-Borel)

A subspace A of \mathbb{R}^n is compact if and only if it is closed and bounded (in either the euclidean metric or square metric).

Functions on Compact Spaces**Theorem 8.6. (Extreme Value Theorem)**

Let $f : X \rightarrow Y$ be continuous, X is compact, and Y is ordered. There exists $c, d \in X$ such that $f(c) \leq f(x) \leq f(d)$ for all $x \in X$.

Theorem 8.7. (Lebesgue Number Lemma)

Let \mathcal{A} be an open covering of a metric space (X, d) . If X is compact, there exists $\delta > 0$ such that any subset of X with diameter (supremum of pairwise distances) less than δ admits an element of \mathcal{A} containing it. Here δ is a **Lebesgue number** for \mathcal{A} .

Definition 8.3. A function f from metric space (X, d_X) to metric space (Y, d_Y) is **uniformly continuous** if for all $\varepsilon > 0$ there exists $\delta > 0$ such that

$$d_X(x, y) < \delta \Rightarrow d_Y(f(x), f(y)) < \varepsilon.$$

Theorem 8.8. (Heine-Cantor)

A continuous function on a compact space is uniformly continuous.

Theorem 8.9. A nonempty compact Hausdorff space with no isolated points (where $\{x\}$ is open) is uncountable. (Hence $[0, 1]$ is uncountable)

Proof. Let $\{x_n\}_{n \in \mathbb{N}^*}$ be an enumeration of X . Let $V_0 = X$. Given the nonempty open set V_{n-1} , choose V_n to be a nonempty open set such that $V_n \subseteq V_{n-1}$ and $x_n \notin \overline{V_n}$: We can choose this by using the Hausdorff condition on x_n and some other point in V_{n-1} , and then take the intersection of V_{n-1} and the neighborhood around this other point. The nested sequence

$$\overline{V_1} \supseteq \overline{V_2} \supseteq \cdots$$

satisfies the finite intersection property and hence by compactness there exists $x \in \bigcap_n \overline{V_n}$. Such an x cannot be any x_n , because $x_n \notin \overline{V_n}$ but $x \in \overline{V_n}$. ■

Limit Point Compactness and Sequential Compactness

Definition 8.4.

- X is **limit point compact** if every infinite subset of X has a limit point.
- X is **sequentially compact** if every sequence of points in X admits a convergent subsequence.

Theorem 8.10. When X is metrizable, all three forms of compactness are equivalent.

Proof. (Compact \Rightarrow Limit Point Compact) Let X be compact and say $A \subseteq X$ has no limit points; we prove that A is finite. Since A vacuously contains all limit points, A is closed. Plus, since no element of A is a limit point, every $a \in A$ admits a neighborhood U_a that only intersects A at a alone. $\{X - A\} \cup \{U_a\}_{a \in A}$ is now an open covering of X , and hence admits a finite subcovering. This shows that A is finite. (True even for non-metric spaces)

(Limit Point Compact \Rightarrow Sequentially Compact) Let X be limit point compact and let $\{x_n\}_{n \in \mathbb{N}}$ be a sequence in X . If $\{x_n : n \in \mathbb{N}\}$ is finite, then some element repeats infinitely often, i.e. a trivial subsequence. If not, then $\{x_n : n \in \mathbb{N}\}$ has a limit point x . Repeatedly taking arbitrarily small ε -balls of x gives a subsequence converging to it.

(Sequentially Compact \Rightarrow Compact) Let \mathcal{A} be an open covering. We prove two properties:

- X has a Lebesgue number:
Assume not, so for each $n \in \mathbb{N}^*$ there exists some C_n with diameter $< 1/n$ that is not contained in any element of \mathcal{A} . Choose an $x_n \in C_n$ for each n , and say some subsequence x_{n_i} converges to x . \mathcal{A} contains some A that contains x , and we can pick some $B(x, 2/n_N) \subseteq A$. Pick $M \geq N$ such that $d(x_{n_M}, x) < 1/n_N$. Now since C_{n_M} has diameter $< 1/n_N$, any $c \in C_{n_M}$ satisfies $d(c, x) \leq d(c, x_{n_M}) + d(x_{n_M}, x) < 1/n_N + 1/n_N = 2/n_N$ and hence $C_{n_M} \subseteq A$, a contradiction.
- X is **totally bounded** (can be finitely covered by ε -balls for any $\varepsilon > 0$):
Let $\varepsilon > 0$ and $x_0 \in X$. Assume X cannot be finitely covered by ε -balls. Then we can always pick x_{n+1} not in $B(x_1, \varepsilon) \cup \dots \cup B(x_n, \varepsilon)$, giving a sequence where pairs of points differ by $\geq \varepsilon$, a contradiction.

Now let δ be a Lebesgue number for \mathcal{A} . Let U_1, \dots, U_k be a finite covering of $(\delta/3)$ -balls. Then the diameter of each U_i is $< \delta$, so each U_i is contained within some $A_i \in \mathcal{A}$. Then $\{A_1, \dots, A_k\}$ is a finite subcovering. Hence X is compact. ■

9 Countability Axioms

Definition 9.1.

- **1st Countability Axiom:** There is a countable basis at every $x \in X$, i.e. for each x there exists countably many neighborhoods $\{U_n\}_{n \in \mathbb{N}}$ so that any neighborhood of x contains some U_n .
- **2nd Countability Axiom:** There is a countable basis for X .
- **Lindelöf:** Every open covering admits a *countable* subcovering.
- **Separable:** There is a countable dense subset. (**Dense** means the closure is X)

Theorem 9.1. 2nd Countability implies the other three.

10 Separation Axioms

Definition 10.1. A topological space X is said to satisfy the **T_1 Axiom** if all singleton sets are closed. Assuming X is T_1 , we say that it could satisfy

- **T_2 (Hausdorff):** For each pair of distinct points $x_1, x_2 \in X$, there exist neighborhoods U_1, U_2 respectively that are disjoint.
- **T_3 (Regular):** For any $x \in X$ and closed set A of X not containing x , there exist open sets U_1, U_2 containing $\{x\}, A$ respectively and are disjoint.
- **T_4 (Normal):** For each pair of disjoint closed sets A, B of X , there exist open sets U_1, U_2 containing A, B respectively and are disjoint.

Theorem 10.1. Normal \Rightarrow Regular \Rightarrow Hausdorff (recall T_1 is assumed)

Theorem 10.2.

- X is regular if and only if for any $x \in X$ and neighborhood U , there exists a neighborhood V such that $\bar{V} \subseteq U$.
- X is normal if and only if for any closed A and open $U \supseteq A$, there exists an open set $V \supseteq A$ such that $\bar{V} \subseteq U$.

Theorem 10.3. T_2 and T_3 are preserved under subspaces and products.

Example 10.1. \mathbb{R}_ℓ is normal but the *Sorgenfrey plane* \mathbb{R}_ℓ^2 is not normal.

Theorem 10.4.

Compact Hausdorff spaces, metrizable spaces, and well-ordered spaces are normal.

Urysohn Lemma

Theorem 10.5. (Urysohn Lemma)

Let X be normal and A, B be disjoint closed sets of X . There exists a continuous map

$$f : X \rightarrow [0, 1]$$

such that $f(A) = \{0\}$ and $f(B) = \{1\}$.

Proof. Define open sets U_p for each $p \in \mathbb{Q} \cap [0, 1]$ as follows: Enumerate $\mathbb{Q} \cap [0, 1]$ such that 1 and 0 are the first two elements. Define $U_1 = X - B$ and by normality pick U_0 such that $A \subseteq U_0 \subseteq \overline{U_0} \subseteq U_1$. By induction, say we defined U_p for a finite number of p 's and let r be the next rational in the enumeration. We must have $p < r < q$ where U_p, U_q are already defined. By normality we pick U_r such that $\overline{U_p} \subseteq U_r \subseteq \overline{U_r} \subseteq U_q$.

Additionally, we let $U_p = \emptyset$ for all rationals $p < 0$ and $U_p = X$ for all rationals $p > 1$. Hence,

$$p < q \Rightarrow \overline{U_p} \subseteq U_q.$$

We then define $f(x) = \inf \{p : x \in U_p\}$. It is easy to see $f(A) = \{0\}$ and $f(B) = \{1\}$. We show that f is continuous.

Lemma 1. $x \in \overline{U_r} \Rightarrow f(x) \leq r$

Proof. If $x \in \overline{U_r}$, then $x \in U_s$ for every $s > r$. Hence $f(x) \leq r$. □

Lemma 2. $x \notin \overline{U_r} \Rightarrow f(x) \geq r$.

Proof. If $x \notin \overline{U_r}$, then $x \notin U_s$ for any $s < r$. Hence $f(x) \geq r$. □

Given a ball $I = (f(x) - \delta, f(x) + \delta)$, we wish to find a neighborhood U of x such that $f(U) \subseteq I$. First we choose rational numbers $p, q \in I$ such that $p < f(x) < q$. Then the open set $U_q \setminus \overline{U_p}$ is the desired neighborhood using the lemmas above. ■

Urysohn Metrization Theorem

Theorem 10.6. Every Lindelöf regular space is normal.

Proof. Let X be Lindelöf and regular, and let A and B be closed in X . Since B is closed, each point $a \in A$ has a neighborhood U'_a not intersecting B . Using regularity (Theorem 10.2), pick a neighborhood U_a whose closure lies in U'_a . Therefore $\{U_a\}_{a \in A}$ is an open covering of A whose closures do not intersect B . Since X is Lindelöf, there is a countable subcovering $\{U_n\}_{n \in \mathbb{N}}$. Similarly, choose a countable open covering $\{V_n\}_{n \in \mathbb{N}}$ of B where each $\overline{V_n}$ is disjoint from A .

The sets $U = \bigcup U_n$ and $V = \bigcup V_n$ are open sets containing A and B respectively, but they may not be disjoint. We define for each $n \in \mathbb{N}$,

$$U_n^* = U_n \setminus \bigcup_{i=1}^n \overline{V_i} \quad \text{and} \quad V_n^* = V_n \setminus \bigcup_{i=1}^n \overline{U_i}.$$

(Exercise) Then $U^* = \bigcup U_n^*$ and $V^* = \bigcup V_n^*$ are disjoint open sets containing A and B respectively. ■

Theorem 10.7. (Urysohn Metrization Theorem)

Every 2nd countable regular space is metrizable.

Proof. Let X be regular with a countable basis \mathcal{B} . From Example 5.1, it suffices to imbed X into \mathbb{R}^ω . We first prove a lemma:

Lemma. There exists a collection $\{f_n : X \rightarrow [0, 1]\}_{n \in \mathbb{N}}$ of continuous functions such that given any $x \in X$ and any neighborhood U , there exists some f_n that is positive at x but vanishes outside U .

Proof. For each $B, C \in \mathcal{B}$ with $\overline{B} \subseteq C$, apply the Urysohn Lemma to construct a continuous function $g_{B,C} : X \rightarrow [0, 1]$ such that $g_{B,C}(\overline{B}) = \{1\}$ and $g_{B,C}(X \setminus C) = \{0\}$. $\{g_{B,C} : \overline{B} \subseteq C\}$ is the desired collection. It is countable because $\mathcal{B} \times \mathcal{B}$ is countable, and given any x with neighborhood U , we can choose by regularity and definition of basis the sequence of open sets $x \in B \subseteq \overline{B} \subseteq C \subseteq U$, and then use $g_{B,C}$. □

Using $\{f_n\}_{n \in \mathbb{N}}$ from the Lemma, define $F : X \rightarrow \mathbb{R}^\omega$ such that

$$F(x) = (f_0(x), f_1(x), f_2(x), \dots)$$

Firstly, F is continuous because each component is continuous and \mathbb{R}^ω has the *product* topology. Secondly, F is injective because given $x \neq y$, there exists some $f_n(x) > 0 = f_n(y)$ (X is Hausdorff!). It remains to show that for each open set U in X , $F(U)$ is open in $F(X)$.

Let $x \in U$ and $f(x) = z$. Choose a f_N that is positive at x but vanishes outside U . Let

$$W = F(X) \cap \pi_N^{-1}((0, +\infty))$$

be open in $F(X)$. We claim that $z \in W \subseteq F(U)$. Firstly, we have $z = F(x) \in W$ because $f_N(x) > 0$. Secondly, given any $F(y) \in W$, we must have $f_N(y) > 0$. Since f_N vanishes outside U , y must be in U , so $F(y) \in F(U)$. ■

Tietze Extension Theorem

Theorem 10.8. (Tietze Extension Theorem)

Let X be normal and A be closed in X . Any continuous map from A to $[-1, 1]$ can be extended to a continuous map from X to $[-1, 1]$. True also for \mathbb{R} instead of $[-1, 1]$.

Proof.

Lemma. If $f : A \rightarrow [-\varepsilon, \varepsilon]$ is continuous, there exists continuous $g : X \rightarrow \mathbb{R}$ with $g(X) \subseteq [-\varepsilon/3, \varepsilon/3]$ and $(g - f)(A) \subseteq [-2\varepsilon/3, 2\varepsilon/3]$.

Proof. Applying the Urysohn Lemma on the disjoint closed sets $L = f^{-1}([-\varepsilon, -\varepsilon/3])$ and $R = f^{-1}([\varepsilon/3, \varepsilon])$, there exists $g : X \rightarrow [-\varepsilon/3, \varepsilon/3]$ such that $g(L) = \{-\varepsilon/3\}$ and $g(R) = \{\varepsilon/3\}$. This g works. □

Now let $f : A \rightarrow [-1, 1]$ be continuous. Then we can find $g_1 : X \rightarrow [-1/3, 1/3]$ such that $|f(a) - g_1(a)| \leq 2/3$ for all $a \in A$. Then we apply the Lemma on $f - g_1$ again, so we get $g_2 : X \rightarrow [-2/9, 2/9]$ such that $|f(a) - g_1(a) - g_2(a)| \leq 4/9$. Recursively, we get a sequence of functions g_n such that $g_{n+1} : X \rightarrow [-(2/3)^n/3, (2/3)^n/3]$ and

$$|f(a) - g_1(a) - \cdots - g_{n+1}(a)| \leq \left(\frac{2}{3}\right)^{n+1}.$$

By the Weierstrass M -test, $g(x) = \sum_{n=1}^{\infty} g_n(x)$ converges to the desired function (Exercise).

To show the \mathbb{R} version, it suffices to show the $(-1, 1)$ version since they are homeomorphic. Take g from the $[-1, 1]$ case. Apply the Urysohn Lemma to the disjoint closed sets A and $D = g^{-1}(\{-1\}) \cup g^{-1}(\{1\})$ to get a continuous $\varphi : X \rightarrow [0, 1]$ so that $\varphi(D) = \{0\}$ and $\varphi(A) = \{1\}$. Then $h(x) = \varphi(x)g(x)$ works. ■

11 Manifolds

Definition 11.1. An ***m*-manifold** is a 2nd countable Hausdorff space X such that each $x \in X$ has a neighborhood homeomorphic with an open subset of \mathbb{R}^m . A 1-manifold is a ***curve***, and a 2-manifold is a ***surface***.

Definition 11.2. The ***support*** of $\varphi : X \rightarrow \mathbb{R}$ is the closure of $\varphi^{-1}(\mathbb{R} \setminus \{0\})$

Definition 11.3. Let $\{U_1, \dots, U_n\}$ be an open covering of X . The collection of continuous functions $\{\varphi_1, \dots, \varphi_n\}$ from X to $[0, 1]$ is a ***partition of unity*** dominated by $\{U_i\}$ if

- $(\text{support } \varphi_i) \subseteq U_i$ for $1 \leq i \leq n$.
- $\sum_{i=1}^n \varphi_i(x) = 1$ for each $x \in X$.

Theorem 11.1. Any finite open covering $\{U_i\}$ of a normal space X dominates some partition of unity $\{\varphi_i\}$.

Proof. We first find a finite open covering $\{V_i\}$ such that $\overline{V_i} \subseteq U_i$. We start by using normality to choose an open set V_1 containing $X \setminus (U_2 \cup \dots \cup U_n)$ and whose closure is contained in U_1 . Then we recursively pick an open set V_k containing $X \setminus (V_1 \cup \dots \cup V_{k-1} \cup U_{k+1} \cup \dots \cup U_n)$ and whose closure is contained in U_k .

Repeat the procedure for $\{V_i\}$, giving an open covering $\{W_i\}$ such that $\overline{W_i} \subseteq V_i$. Now pick, by the Urysohn lemma, a continuous function $\psi_i : X \rightarrow [0, 1]$ such that $\psi_i(\overline{W_i}) = \{1\}$ and $\psi_i(X \setminus V_i) = \{0\}$. Hence $\overline{\psi_i^{-1}(\mathbb{R} \setminus \{0\})} \subseteq \overline{W_i} \subseteq V_i \subseteq U_i$. Then $\varphi_i(x) = \psi_i(x) / \sum_{i=1}^n \psi_i(x)$ is a desired partition of unity. ■

Theorem 11.2. A compact m -manifold X can be imbedded in \mathbb{R}^N for some $N \in \mathbb{N}$.

Proof. Since X is compact, we can cover X with a finite open covering $\{U_i\}$ each imbeddable in \mathbb{R}^m . Let the imbeddings be $g_i : U_i \rightarrow \mathbb{R}^m$ and a partition of unity be $\varphi_i : U_i \rightarrow [0, 1]$. Let h_i be the continuous function

$$h_i(x) = \begin{cases} \varphi_i(x)g_i(x) & \text{for } x \in U_i \\ (0, \dots, 0) & \text{for } x \notin \text{support } \varphi_i \end{cases}.$$

Then $F(x) = (\varphi_1(x), \dots, \varphi_n(x), h_1(x), \dots, h_n(x))$ is an imbedding of X into $\mathbb{R}^{n(m+1)}$. ■

12 Paracompactness

Definition 12.1.

- A collection \mathcal{A} of subsets of X is **locally finite** in X if every $x \in X$ has a neighborhood that intersects only finitely many elements of \mathcal{A} .
- A collection \mathcal{B} of subsets of X is **countably locally finite** if $\mathcal{B} = \bigcup_{n=1}^{\infty} \mathcal{B}_n$ where each \mathcal{B}_n is locally finite.
- A collection \mathcal{B} of subsets of X is a **refinement** of a collection \mathcal{A} of subsets of X if each element of \mathcal{B} is contained in some element of \mathcal{A} .
- A space X is **paracompact** if every open covering of X has a locally finite open refinement that covers X .

Example 12.1. \mathbb{R}^n is paracompact. Let $B(r)$ be the open ball of radius r centered at the origin. Given any open covering \mathcal{A} , for each $n \in \mathbb{N}^*$ we can pick a finite number of elements of \mathcal{A} that covers $\overline{B(n)}$. Intersect them with $\mathbb{R}^n \setminus \overline{B(n-1)}$. The union of these open sets is a desired locally finite refinement.

Theorem 12.1. If \mathcal{A} is a locally finite collection of subsets of X , then the collection $\mathcal{B} = \{\overline{A}\}_{A \in \mathcal{A}}$ of closures of elements of \mathcal{A} is also locally finite, and $\overline{\bigcup \mathcal{A}} = \bigcup \mathcal{B}$.

Theorem 12.2. If X is regular, the following are equivalent:

1. X is paracompact.
2. Every open covering of X has a *countably* locally finite *open* refinement that covers X .
3. Every open covering of X has a locally finite refinement (not necessarily open) that covers X .

We generalize Definition 11.2 to partitions of unity of an arbitrary open covering of X .

Definition 12.2. Let $\{U_\alpha\}_{\alpha \in J}$ be an open covering of X . The collection of continuous functions $\{\varphi_\alpha\}_{\alpha \in J}$ from X to $[0, 1]$ is a **partition of unity** dominated by $\{U_\alpha\}_{\alpha \in J}$ if

- $(\text{support } \varphi_\alpha) \subseteq U_i$ for all $\alpha \in J$.
- $\{\text{support } \varphi_\alpha\}_{\alpha \in J}$ is locally finite.
- $\sum_{\alpha \in J} \varphi_\alpha(x) = 1$ for each $x \in X$. This is well-defined due to the second property.

Theorem 12.3. Let X be a paracompact Hausdorff space and $\{U_\alpha\}_{\alpha \in J}$ be an open covering. There exists a **precise refinement** subcovering $\{V_\alpha\}_{\alpha \in J}$ of $\{U_\alpha\}_{\alpha \in J}$: One that satisfies $\overline{V_\alpha} \subseteq U_\alpha$ for all $\alpha \in J$.

Theorem 12.4. Any open covering $\{U_\alpha\}_{\alpha \in J}$ of a paracompact Hausdorff space X dominates some partition of unity $\{\varphi_\alpha\}_{\alpha \in J}$.

13 Baire Spaces

Definition 13.1. A space X is a **Baire space** if, given any countable collection $\{A_n\}$ of closed sets that has an empty interior, their union $\bigcup A_n$ also has an empty interior. (Equivalently, given any countable collection $\{U_n\}$ of dense open sets, their intersection $\bigcap U_n$ is also dense.)

Theorem 13.1. (Baire Category Theorem)

Compact Hausdorff spaces and complete metric spaces are Baire spaces.

14 Dimension Theory

Definition 14.1.

- A collection \mathcal{A} of sets of a space X has **order** $\max_{x \in X} |\{A \in \mathcal{A} : x \in A\}|$.
- The **topological dimension** of X is

$$\dim X = \max_{\mathcal{A} \text{ open cover } X} \left[\min_{\substack{\mathcal{B} \text{ open refinement} \\ \text{subcover of } \mathcal{A}}} (\text{order of } \mathcal{B}) \right] - 1$$

Example 14.1.

- Any compact subspace of \mathbb{R} has dimension at most 1.

Proof. Note that $\mathcal{C} = \{(n, n+1), (n - \frac{1}{2}, n + \frac{1}{2}) : n \in \mathbb{Z}\}$ has order 2. Let \mathcal{A} be any open covering of a compact subspace X of \mathbb{R} , with some Lebesgue number $\delta > 0$. The image \mathcal{J} of \mathcal{C} under $f : x \mapsto \delta x/2$ is an open covering whose elements have diameter $\delta/2 < \delta$, and hence is an open refinement subcover of \mathcal{A} . Hence

$$\begin{aligned} \dim X &= \max_{\mathcal{A} \text{ open cover } X} \left[\min_{\substack{\mathcal{B} \text{ open refinement} \\ \text{subcover of } \mathcal{A}}} (\text{order of } \mathcal{B}) \right] - 1 \\ &\leq \max_{\mathcal{A} \text{ open cover } X} [2] - 1 = 1. \end{aligned}$$

- $X = [0, 1]$ has dimension 1.

Proof. We show that there is some open covering \mathcal{A} such that any open refinement subcover of \mathcal{A} has order at least 2. Let $\mathcal{A} = \{[0, 1), (0, 1]\}$ and let \mathcal{B} be any open refinement subcovering. Since 0 and 1 cannot belong to the same refinement, \mathcal{B} has at least two elements. Partition \mathcal{B} into two nonempty parts \mathcal{B}_1 and \mathcal{B}_2 . If \mathcal{B} had order 1 then $\bigcup \mathcal{B}_1$ and $\bigcup \mathcal{B}_2$ disconnect $[0, 1]$, a contradiction.

Theorem 14.1.

- If Y is a closed subspace of a finite dimensional space X , then $\dim Y \leq \dim X$.
- If $X = Y \cup Z$ where Y, Z are closed finite dimensional subspaces of X , then $\dim X = \max(\dim Y, \dim Z)$.
- Every compact subspace of \mathbb{R}^N has dimension at most N .

Theorem 14.2. (The Imbedding Theorem)

Every compact metrizable space X of dimension m can be imbedded in \mathbb{R}^{2m+1} .
